Review: non-nutritive sucking decreases length of hospital stay in premature infants

Question
Does non-nutritive sucking improve clinical outcomes in premature infants?

Data sources
Studies were identified by searching Medline and CINAHL (back to 1976) and the Cochrane Controlled Trials Register using the terms infant, premature; intensive care units, neonatal; enteral nutrition; sucking behavior; infant nutrition; gastric emptying; growth; parenteral nutrition; bottle feeding; infant care; infant, low birth weight; somatostatin; crying; oxygen; child development; physical stimulation; taste; infant, newborn; and feeding behavior and the text words “non,” “nutritive,” and “suck.” Bibliographies of articles were reviewed and 2 experts were contacted to identify other published or unpublished studies.

Study selection
Studies were selected if they were experimental or quasi-experimental trials that compared non-nutritive sucking of a pacifier with no provision of non-nutritive sucking in premature infants (<37 weeks gestation) and assessed clinically relevant outcomes (eg, weight gain, length of hospital stay, transition to oral or nipple feedings, heart rate and oxygen saturation, and behavior).

Data extraction
Data were extracted on study design and methods, participants, intervention, and outcomes. Articles were assessed for methodological quality (eg, blinding and completeness of follow up).

Main results
19 studies met the selection criteria, but only randomised trials (n = 13) were included in the analysis. Meta-analyses showed that infants provided with non-nutritive sucking had shorter hospital stays (7 days less) than infants not provided with non-nutritive sucking, but did not differ for weight gain, heart rate, or oxygen saturation (table).

Conclusion
Non-nutritive sucking provided to premature infants reduces the length of hospital stay, but does not affect weight gain, energy intake, heart rate, or oxygen saturation.

Non-nutritive sucking v no provision of non-nutritive sucking for premature infants.6

Commentary

Non-nutritive sucking refers to sucking activity when no fluid or nutrition is delivered to the infant. Delivered via a blind nipple or pacifier, non-nutritive sucking is a clinical intervention used to modulate the behavioural state of preterm infants, purportedly improving transition from gavage to breast or bottle feeding. Non-nutritive sucking has also been promoted as reducing infant (both preterm and full term) distress during painful procedures.1 Questions remain, however, about the effectiveness of this intervention.

Pinelli and Symington used a comprehensive search strategy to identify high quality studies evaluating the effectiveness of non-nutritive sucking on various relevant clinical outcomes. The included studies were limited to those that involved preterm infants only, and thus the results may not be relevant to full term infants. None of the studies measured the negative effects of non-nutritive sucking. Further exploration of the potential negative effects of non-nutritive sucking is warranted given the suggestion that this group of infants may be more susceptible to “nipple confusion.” The term nipple confusion refers to an infant’s difficulty in achieving the correct latching technique and sucking pattern necessary for successful breast feeding, after exposure to an artificial nipple.2

Non-nutritive sucking reduced the length of hospital stay and did not affect various other outcomes. Based on this evidence, nurses in neonatal intensive care units may wish to discuss the introduction of non-nutritive sucking with parents of premature infants. This would be consistent with the increasing utilisation of programmes such as the Newborn Individualized Developmental Care and Assessment Program,1 in which clinicians move from protocol based to relationship based care. The premise of such programmes is that individualised caregiving based on an infant’s current functioning and developmental goals may influence outcomes such as infant health and development, family adaptation, and hospital costs.
